

# Phishing

Phishing is a type of attack where attackers trick individuals in to providing sensitive information by pretending to be a trusted entity.

In a phishing attack, the attacker sends fraudulent messages, often via email, that appear to come from a trusted source.

These messages typically contain links that lead to fake websites designed to steal personal information like usernames and passwords.

To prevent phishing attacks, a reputable email security software should be used. Contact us for guidance on email security software!

Phishing attacks often use urgency or fear tactics, such as claiming an account is compromised or needs immediate action.
